A Guide to Installing EasyCrypt

The official **EasyCrypt** installation instructions are available on the EasyCrypt GitHub repository. We provides a summary of these instructions, with a particular focus on their integration with the Emacs text editor.

EasyCrypt can operate in batch mode from the shell (command line) to check individual . ec files. However, interactive proof construction is conducted within **Emacs**, utilizing the generic interface **Proof General**, which acts as a mediator between **Emacs** and **EasyCrypt**, the latter running as a sub-process of Emacs.

These instructions are aligned with the following software versions:

- **OCaml** compiler version 5.1.1
- **Why3** version 1.7.2
- Alt-ergo version 2.5.2

EasyCrypt is implemented in **OCaml**. **Why3** serves as the interface to **SMT** solvers used by **EasyCrypt**, and **Alt-ergo** is one of the **SMT** solvers required for its operation.

Installing Emacs

You'll first need to make sure autoconf is already installed on your system. Type which autoconf to find out.

```
@:~$ sudo apt-get install autoconf
```

```
@:~$ sudo apt-get install autoconf
```

Installing EasyCrypt

- opam init: creates .opam sub-directory of your home directory
- eval \$(opam env): updates environment variables in current shell

```
@:~$ sudo apt-get install opam
@:~$ opam init
@:~$ eval $(opam env)
```

• opam switch create 5.1.1: say which version of OCaml compiler to build

```
@:~$ opam switch create 5.1.1
* installed base-bigarray.base
. . .
Done.
@:~$ eval $(opam env)
```

```
@:~$ opam pin -yn add easycrypt https://github.com/EasyCrypt/easycrypt.git
Package easycrypt does not exist, create as a NEW package? [Y/n] y
[easycrypt.~dev] synchronised (git+https://github.com/EasyCrypt/easycrypt.git)
easycrypt is now pinned to git+https://github.com/EasyCrypt/easycrypt.git (
  version ~dev)
@:~$ opam install --deps-only easycrypt
[easycrypt.~dev] synchronised (no changes)
The following actions will be performed:
* install conf-gmp
* installed why3.1.7.1
Done.
@:~$ eval $(opam env)
```

```
@:~$ CHECK_IF_PREINSTALLED=false opam install --deps-only easycrypt
[NOTE] It seems you have not updated your repositories for a while. Consider
updating them with:
opam update
[easycrypt.~dev] synchronised (no changes)
Nothing to do.
```

```
@:~$ opam pin why3 1.7.1
@:~$ why3 --version
Why3 platform, version 1.7.1
@:~$ alt-ergo --version
v2.5.2
```

```
@:~$ opam install easycrypt
@:~$ eval $(opam env)
```

There are binaries at this URL https://github.com/Z3Prover/z3/releases/tag/ z3-4.12.4. If you need to build it from source, there are source archives available, too. Assuming you have the binary distribution, put the whole directory somewhere, and update your shell's startup script to add its bin directory to the PATH environment variable. Run which z3 while not in the Z3 bin directory to verify that you have set up PATH correctly.

export PATH="/home/username/z3-4.12.4-x64-glibc-2.35/bin:\$PATH"

```
@:~$ which z3
/home/username/z3-4.12.4-x64-glibc-2.35/bin/z3
```

```
@:~$ opam install easycrypt
@:~$ eval $(opam env)
@:~$ which easycrypt
/home/username/.opam/5.1.1/bin/easycrypt
@:~$ easycrypt why3config
Executing: why3 config detect -C /home/username/.config/easycrypt/why3.conf
Found prover Alt-Ergo version 2.5.2, OK.
Found prover Alt-Ergo version 2.5.2 (alternative: BV)
Found prover Alt-Ergo version 2.5.2 (alternative: counterexamples)

1 Preliminaries

1.1 Cryptosystem and Encryption Scheme

- A **cryptosystem** is the abstract formal definition encompassing all components necessary for secure communication.
- An **encryption scheme** specifies the algorithms (or protocols) used to implement encryption and decryption within a cryptosystem.

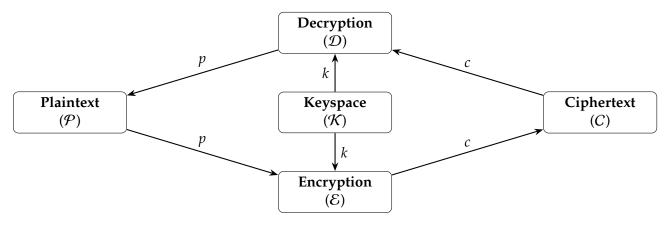

Figure 1: Cryptosystem

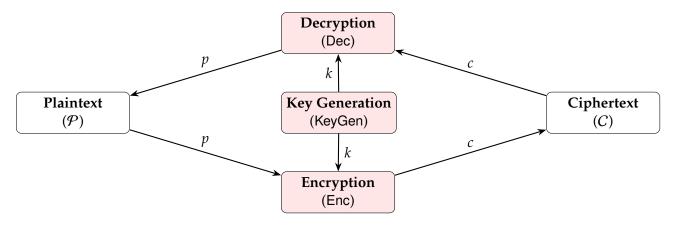

Figure 2: Encryption Scheme

Cryptosystem

Definition 1. A **cryptosystem** is a five-tuple

$$(\mathcal{P}, \mathcal{C}, \mathcal{K}, \mathcal{E}, \mathcal{D}),$$

where

- (i) $\boxed{\mathcal{P}}$ is a finite set of all possible plaintexts^a.
- (ii) \overline{C} is a finite set of all possible ciphertexts^b.
- (iii) \mathcal{K} is a finite set of all possible keys^c.
- (iv) $\boxed{\mathcal{E}: \mathcal{K} \times \mathcal{P} \to C}$ is a deterministic function that maps a key $k \in \mathcal{K}$ and a plaintext $p \in \mathcal{P}$ to a ciphertext $c \in C$. Formally:

$$\begin{array}{cccc} \mathcal{E} & : & \mathcal{K} \times \mathcal{P} & \longrightarrow & C \\ & (k,p) & \longmapsto & c \end{array}.$$

(v) $\boxed{\mathcal{D}: \mathcal{K} \times C \to \mathcal{P}}$ is a deterministic function that maps a key $k \in \mathcal{K}$ and a ciphertext $c \in C$ to a ciphertext $p \in \mathcal{P}$. Formally:

$$\mathcal{D} : \mathcal{K} \times C \longrightarrow \mathcal{P} \atop (k,c) \longmapsto p.$$

Remark 1 (Correctness Property). For every key $k \in \mathcal{K}$ and every plaintext $p \in \mathcal{P}$, the decryption function is the inverse of the encryption function. That is:

$$\mathcal{D}(k,\mathcal{E}(k,p))=p.$$

Remark 2 (Security). The security of the cryptosystem is defined with respect to a particular adversarial model. Informally, a cryptosystem is secure if an adversary with limited computational resources cannot distinguish between the ciphertexts of any two plaintexts, even if they know the encryption algorithm but do not know the key.

^aThese are the possible inputs to the encryption algorithm and typically represent meaningful data to be protected.

 $[^]b$ These are the encrypted outputs of the encryption algorithm corresponding to plaintexts in \mathcal{P} .

^cEach key $k \in \mathcal{K}$ determines a specific encryption and decryption function.

Encryption Scheme

Definition 2. An **encryption scheme** is a three-tuple

$$\Pi := (KeyGen, Enc, Dec).$$

where

(i) KeyGen is a probabilistic algorithm that ouputs a key $k \in \mathcal{K}$, where \mathcal{K} is the key space. Formally:

$$\mathsf{KeyGen}: \{0,1\}^* \to \mathcal{K},$$

where $\{0,1\}^*$ is the set of binary strings of arbitrary length (representing randomness or input seed). The ouput k is uniformly distributed over \mathcal{K} .

(ii) Enc is a (possibly probabilistic) algorithm that takes a key $k \in \mathcal{K}$ and a message $p \in \mathcal{M}$ (message space) and outpus a ciphertext $c \in \mathcal{C}$ (ciphertext sapce). Formally:

$$\mathsf{Enc}: \mathcal{K} \times \mathcal{M} \times \{0,1\}^* \to C.$$

The algorithm may use randomness (from $\{0,1\}^*$) to ensure that repeated encryptions of the same message $m \in \mathcal{M}$ under the same key $k \in \mathcal{K}$ yield different ciphertexts c.

(iii) Dec is a deterministic algorithms that takes a key $k \in \mathcal{K}$ and a ciphertext $c \in C$ and outust the corresponding message $m \in \mathcal{M}$. Formally:

$$\operatorname{Dec}:\mathcal{K}\times\mathcal{C}\to\mathcal{M}$$
.

Remark 3 (Correctness Property). For every $k \in \mathcal{K}$, $m \in \mathcal{M}$, and $c \in \mathcal{C}$, the scheme must satisfy

$$Dec(k, Enc(k, m; r)) = m$$

where r represents the random bits used by Enc.

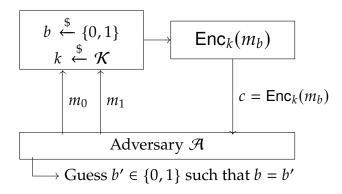

Remark 4 (Security). The security of an encryption scheme depends on the adversarial model. For **semantic security**, an encryption scheme must satisfy the following:

"Given a ciphertext c, no computationally bounded adversary can distinguish between encryptions of any two messages m_0 , m_1 , even if they are chosen adaptively by the adversary."

Example 1 (IND-CPA).

The indistinguishability under chosen plaintext attack (IND-CPA) model:

- 1. The adversary chooses two messages m_0 , m_1 .
- 2. A random bit $b \in \{0,1\}$ is chosen, and the ciphertext $c = \text{Enc}(k, m_b)$ is provided to the adversary.
- 3. The adversary outputs a guess $b' \in \{0, 1\}$.

The scheme is secure if the adversary's advantage is negligible:

$$\operatorname{Adv}_{\Pi}^{\operatorname{IND-CPA}}(\mathcal{A}) := \left| \Pr[b' = b] - \frac{1}{2} \right| \le \operatorname{negl}(\lambda),$$

where λ is the security parameter.

1.2 Perfect Security

Note (Measure Theory). Let $(\Omega, \mathcal{F}, Pr)$ be a probability space, where:

- Ω is the sample space representing all possible outcomes.
- \mathcal{F} is a σ -algebra of subsets of Ω , representing the events.
- $Pr : \mathcal{F} \to [0, 1]$ is a probability measure satisfying $Pr[\Omega] = 1$.

Note (Random Variables).

• A **plaintext random variable** $X: \Omega \to \mathcal{P}$ is a measurable function, i.e.,

$$X^{-1}[A] \in \mathcal{F}$$
, $\forall A \subseteq \mathcal{P}$, where *A* is measurable.

This means X maps outcomes in Ω to plaintexts in a way consistent with the probability structure. The distribution of X, denoted P_X , is the pushforward measure of P under X:

$$P_X(A) = P(X \in A) = P(\left\{\omega \in \Omega : X(\omega) \in A\right\}),$$

for all measurable subsets $A \subseteq \mathcal{P}$.

• A **ciphertext random variable** $Y : \Omega \to C$ is a measurable function, i.e.,

$$Y^{-1}[B] \in \mathcal{F}$$
, $\forall B \subseteq C$, where *B* is measurable.

This means Y maps outcomes in Ω to ciphertexts in a measurable way. The distribution of Y, denoted P_Y , is the pushforward measure of P under Y:

$$P_Y(B) = P(Y \in B) = P(\{\omega \in \Omega : Y(\omega) \in B\}),$$

for all measurable subsets $B \subseteq C$.

• A random variable for the key space $K : \Omega \to \mathcal{K}$ is a measurable function, i.e.,

$$K^{-1}[A] \in \mathcal{F}$$
, $\forall A \subseteq \mathcal{K}$, where *K* is measurable.

This means K maps outcomes in the sample space Ω to keys in K in a way consistent with the probability structure. The distribution of K, denoted P_K , is the pushforward measure of P under K:

$$P_K(A) = P(K \in A) = P(\{\omega \in \Omega : K(\omega) \in A\}),$$

for all measurable subsets $A \subseteq \mathcal{K}$.

Note. If the key is selected uniformly from \mathcal{K} , then $P_K(A)$ is proportional to the size of A:

$$P_K(A) = \frac{|A|}{|\mathcal{K}|}, \quad \forall A \subseteq \mathcal{K}.$$

Perfect Security of an Encryption Scheme

Definition 3. An encryption scheme $\Pi = (\text{KeyGen, Enc, Dec})$ is **perfect security** if, for every $m \in \mathcal{M}$, $c \in \mathcal{C}$, and $k \in \mathcal{K}$ such that Enc(k, m) = c, the following holds:

(i) Ciphertext Independence:

$$\Pr[M = m \mid C = c] = \Pr[M = m],$$

where

- *M* is the random variable representing the plaintext.
- *C* is the random variable representing the ciphertext.
- (ii) **Key Uniformity**: The key *K* must satisfy:

$$Pr[Enc(K, m) = c] = Pr[C = c],$$

for all $m \in \mathcal{M}$, $c \in C$, and uniformly random K.

Remark 5.

$$Pr[M = m \mid C = c] = Pr[M = m] \iff Pr[C = c \mid M = m] = Pr[C = c]$$

Theorem 1. *Consider a cryptosystem* (P, C, K, E, D) *where*

$$|\mathcal{P}| = |C| = |\mathcal{K}|$$
.

Then the cryptosystem (or encryption scheme) has perfect security if and only if

- (i) every key is used with equal probability $1/|\mathcal{K}|$, and
- (ii) $\forall x \in \mathcal{P}$, $\forall y \in \mathcal{C}$, $\exists ! k \in \mathcal{K}$ such that $\mathcal{E}_k(x) = y$.

Proof. (\Rightarrow) By definition of perfect security,

$$Pr[X = x \mid Y = y] = Pr[X = x], \quad \forall x \in \mathcal{P}, y \in C.$$

(i) Let *K* be the random variable representing the key. Since the ciphertext *y* is determined by the key *k* and the plaintext *x*, we have:

$$\Pr[Y = y \mid X = x] = \Pr[\exists k \in \mathcal{K} \text{ such that } \mathcal{E}_k(x) = y].$$

To achieve uniform distribution of Y for any fixed x, every key must be equality likely:

$$\Pr[K = k] = \frac{1}{|\mathcal{K}|}, \quad \forall k \in \mathcal{K}.$$

(ii) Assume that there exists two distinct keys $k_1, k_2 \in \mathcal{K}$, with $k_1 \neq k_2$, such that

$$\mathcal{E}_{k_1}(x)=y=\mathcal{E}_{k_2}(x),$$

for some $x \in \mathcal{P}$ and $y \in C$.

TBA

 (\Leftarrow) Using Bayes' Theorem:

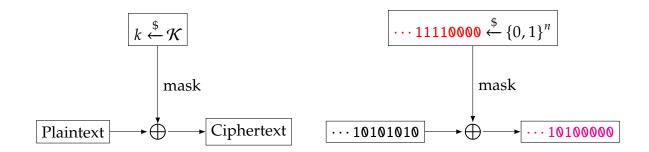

$$\Pr[X = x \mid Y = y] = \frac{\Pr[Y = y \mid X = x] \Pr[X = x]}{\Pr[Y = y]}.$$

Example 2 (One-Time Pad). The one-time pad encryption scheme is perfect security.

- $\mathcal{M} = C = \mathcal{K} = \{0,1\}^n$;
- $Enc(k, m) = m \oplus k$, where \oplus is bitwise XOR;
- $Dec(k, c) = c \oplus k$.

We must show that $Pr[C = c \mid M = m] = Pr[C = c]$. For $m \in \mathcal{M}$ and $c \in C$,

$$\Pr[C = c \mid M = m] = \sum_{k \in \mathcal{K}} \Pr[K = k]$$

Theorem 2. The one-time pad encryption scheme is perfectly secret.

Proof.

$$Pr[C = c \mid M = m] = Pr[c = Enc(K, m)] = Pr[c = m \oplus K]$$
$$= Pr[K = m \oplus c]$$
$$= 2^{-n} \quad \text{if } K \xleftarrow{\$} \mathcal{K} = \{0, 1\}^n$$

Fix any distribution over \mathcal{M} . For any $c \in C$, we have

$$Pr[C = c] = \sum_{m \in \mathcal{M}} Pr[C = c \mid M = m] \cdot Pr[M = m]$$
$$= 2^{-n} \cdot Pr[M = m]$$

By Bayes' Theorem, we obtain

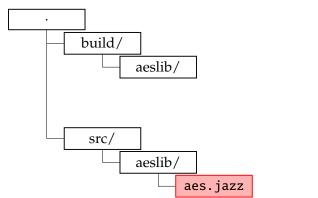

$$\Pr[M = m \mid C = c] = \frac{\Pr[C = c \mid M = m] \cdot \Pr[M = m]}{\Pr[C = c]}$$
$$= \frac{2^{-n} \cdot \Pr[M = m]}{2^{-n}}$$
$$= \Pr[M = m].$$

2 Machine-checked Proofs for AES

2.1 Cryptographic Primitive

2.1.1 Build AES Library

Code 1: aes.jazz	Code 2: aes.japp	Code 3: aes.s	
/* Jasmin implementation of		.att_syntax	
AES using AES-NI */		.text	
#ifdef EXPORT_TEST		.p2align 5	
export	export	.globl _aes	
#else		.globl aes	
inline			
#endif		_aes:	
fn aes(reg u128 key, reg u128 in)	fn aes(reg u128 key, reg u128 in)	aes:	
→ reg u128 {	→ reg u128 {		
reg u128 out;	reg u128 out;	vmovdqu %xmm0, %xmm12	
reg u128[11] rkeys;	reg u128[11] rkeys;	vpxor %xmm2, %xmm1, %xmm0	
		aesenc %xmm3, %xmm0	
rkeys = keys_expand(key);	rkeys = keys_expand(key);		
out = aes_rounds(rkeys, in);	out = aes_rounds(rkeys, in);	aesenc %xmm11, %xmm0	
return out;	return out;	aesenclast %xmm12, %xmm0	
}	}	ret	

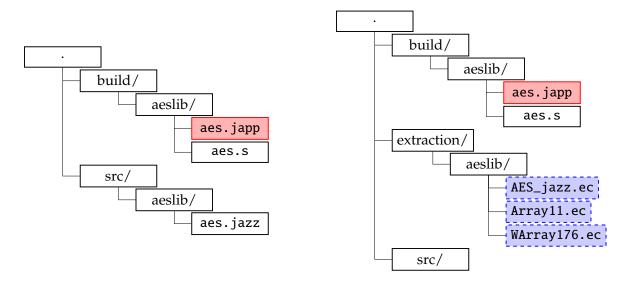

Command 1 :

[cpp]	C Preprocessor	Preprocesses source code files by expanding macros, process- ing conditional compilation direc- tives, and handling file inclusions.
[-nostdinc]	No Standard Include	Prevents the preprocessor from searching in standard system directories for include files, limiting the scope of header file processing to explicitly specified paths or local includes.
[-DEXPORT_TEST]	Define Macro EXPORT_TEST	Defines a preprocessor macro (EXPORT_TEST) that can be used for conditional compilation within the source code.
[/aes.jazz]	Source File Path	Specifies the input Jasmin source code file to be preprocessed.
[1]	Pipe	Passes the output of the cpp command as input to the next command (grep).
[grep -v "^#"]	Global Regular Expression Print (with -v for inverse matching)	Filters out lines starting with #, such as preprocessor directives or comments, from the preprocessed output.
[>]	Output Redirection	Redirects the filtered output from the preprocessing pipeline to a specified file.
[/aes.japp]	Output File Path	Specifies the destination file for the preprocessed Jasmin code.

Command 2 :

[jasminc]	Jasmin Compiler	Compiles Jasmin source code into optimized assembly code.
[/aes.japp]	Input File Path	Specifies the preprocessed Jasmin source file to be compiled.
[-0]	Output File Option	Indicates the output file name or path for the generated assembly code.
[/aes.s]	Output File Path	Specifies the destination file for the generated assembly code.

2.2 Extract AES Library for Correctness and Security

@~\$ jasminc build/aeslib/aes.japp -ec aes -ec invaes -oec AES_jazz.ec
@~\$ mv AES_jazz.ec Array11.ec WArray176.ec extraction/aeslib

[jasminc] The 'jasminc' command in this context extracts verification conditions specifically designed to interface with EasyCrypt, a tool used for formal reasoning about cryptographic security.

[-ec aes -ec invaes] The '-ec' flag specifies functions or modules to extract formal verification constraints from the Jasmin source file.

[-oec AES_jazz.ec] The '-oec' flag specifies the output file where the extracted constraints for the specified modules (aes and invaes) will be saved.

Code 4: Array11.ec

from Jasmin require import JArray.

clone export PolyArray as Array11 with op size <- 11.</pre>

Code 5: WArray176.ec

from Jasmin require import JArray.

clone export PolyArray as Array11 with op size <- 11.</pre>

Code 6: AES_jazz.ec (lines 127-134)

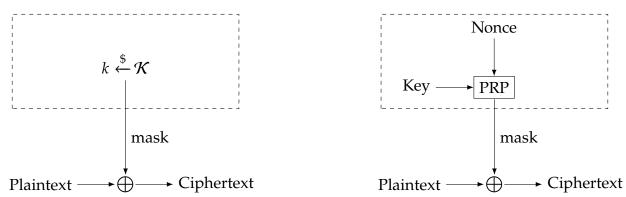

```
proc aes (key:W128.t, in_0:W128.t) : W128.t = {
   var out:W128.t;
   var rkeys:W128.t Array11.t;
   rkeys <- witness;
   rkeys <@ keys_expand (key);
   out <@ aes_rounds (rkeys, in_0);
   return out;
}</pre>
```

2.2.1 Extract AES Library for Constant-time

```
@~$ jasminc build/aeslib/aes.japp -CT -ec aes -ec invaes -oec AES_jazz_ct.ec
@~$ mv AES_jazz_ct.ec Array11.ec WArray176.ec extraction/aeslib
```

2.2.2 Build Nonce-based AES Encryption with register calling convension

2.2.3 Implementation of Nonce-based AES Encryption Scheme

• The **one-time pad (OTP) encryption scheme** is a cryptographic construct that achieves perfect security.

$$\Pi_{OTP} = (KeyGen, Enc, Dec),$$

where

(i)

(ii) Enc: $\mathcal{K} \times \mathcal{M} \to C$: $(k, m) \mapsto c = k \oplus m$;

Enc :
$$\mathcal{K} \longrightarrow \mathcal{C}^{\mathcal{M}}$$
 where $k \mapsto c = \operatorname{Enc}_k(m)$ where $k \mapsto c = \operatorname{Enc}_k(m)$ where $k \mapsto c = k \oplus m$

• A **nonce-based PRP encryption scheme** is a cryptographic construct where a nonce (number used once) is incorporated to ensure unique ciphertexts for the same plaintext under the same key.

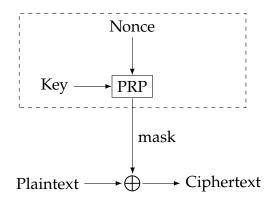

$$\Pi_{\mathcal{N}-PRP} = (KeyGen, Enc, Dec),$$

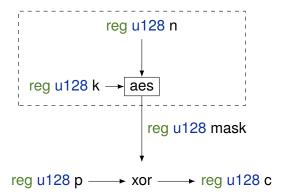

where

(i)

(ii) Enc: $\mathcal{K} \times \mathcal{N} \times \mathcal{M} \to C$: $(k, n, m) \mapsto c = \text{Enc}_k(n) \oplus m$;

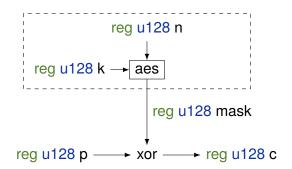

Enc :
$$\mathcal{K} \longrightarrow [\mathcal{N} \to [\mathcal{M} \to C]]$$
 where $c = \operatorname{Enc}_k(n) \oplus m$ where $n \mapsto c = k \oplus m$

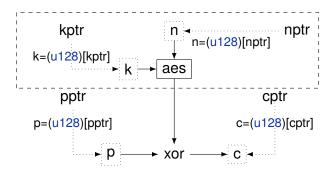

Code 7: src/example/NbAESEnc.jazz

```
/* Nonce-based symmetric encryption for 16-byte messages using AES as a PRF */
/* We use cpp to manage modules in Jasmin */
#include "../aeslib/aes.jazz"
/* We make xor into a function, but this costs nothing because
 Jasmin compiler does not include inlining moves (warning issued o/w). */
inline fn xor(reg u128 a, reg u128 b) \rightarrow reg u128 {
  reg u128 r;
  r = a^b;
  return r;
}
/* These functions can be called from C for testing. */
export fn enc(reg u128 k, reg u128 n, reg u128 p) → reg u128 {
  reg u128 mask,c;
  mask = aes(k,n);
  c = xor(mask,p);
  return(c);
}
export fn dec(reg u128 k, reg u128 n, reg u128 c) → reg u128 {
  reg u128 mask,p;
  mask = aes(k,n);
  p = xor(mask,c);
  return(p);
```

Code 8: src/example/NbAESEnc_mem.jazz

/* Nonce-based symmetric encryption for 16-byte messages using AES as a PRF */

```
#include "../aeslib/aes.jazz"
inline fn xor(reg u128 a, reg u128 b) → reg u128 {
  reg u128 r;
  r = a^b;
  return r;
}
/* These functions can be called from C for testing.
  They receive pointers to byte arrays of length 16.
  Convention is that first pointer is writable for output. */
export fn enc(reg u64 cptr, reg u64 kptr, reg u64 nptr, reg u64 pptr) {
  reg u128 mask,k,n,p,c;
  k = (u128)[kptr];
  n = (u128)[nptr];
  mask = aes(k,n);
  p = (u128)[pptr];
  c = xor(mask,p);
  (u128)[cptr] = c;
}
export fn dec(reg u64 pptr, reg u64 kptr, reg u64 nptr, reg u64 cptr) {
  reg u128 mask,k,n,p,c;
  k = (u128)[kptr];
  n = (u128)[nptr];
  mask = aes(k,n);
  c = (u128)[cptr];
  p = xor(mask,c);
  (u128)[pptr] = p;
```

Code 9: test/test_NbAESEnc.c

```
#include <smmintrin.h>
